Shoegaze Guitar Wall

Sounds like: My Bloody Valentine / Slowdive wash

ACCURACY C

A good approximation, not the real thing.

NOT YET TESTED - settings are a starting point; trust your ears

WHAT YOU NEED (in this order)

`Double-tracked guitar -> CF-101 chorus -> RV7000 (100% wet) -> Scream 4 -> wide panning`

Starting material: DI electric guitar, clean; works better with two takes

---

DO THIS, STEP BY STEP

1. Record the part twice (real doubles, not a copy). Pan take 1 hard left, take 2 hard right.

2. Each side: CF-101 Chorus/Flanger — rate low (~30), feedback 0, delay ~40, sync off. Subtle movement, not seasick.

3. Here's the trick, per side: RV7000 as an INSERT set 60–80% wet, Hall, decay 4 s, THEN Scream 4 after it.

4. Scream 4: Damage type Fuzz, Damage 45–60. Because the reverb feeds the fuzz, the tail distorts and smears into the tone. That's the shoegaze move.

5. Roll off highs after: channel EQ high shelf -3 dB at 8 kHz. Shoegaze walls are dark, not bright.

6. Both sides to a guitar bus; bus comp 2:1, slow attack, 2 dB reduction, just to stop the wall from swallowing the snare.

Why this works

Normal chains distort then reverberate (clean tail). Reversing the order makes the reverb tail itself distort — a continuous sustaining wall.

Why this order

That reversal IS the recipe. Reverb -> distortion. Non-negotiable here.

Reason trick

Automate the RV7000 dry/wet from verse (30%) to chorus (80%) via a Combinator macro for the "the chorus just opened up" effect.

The skill you just learned

Effect-order inversion: putting time-based effects BEFORE gain effects changes the instrument, not just the polish.

Worth buying?
This is a D->C rescue by stock. For a real B: a proper fuzz + reverse reverb RE or VST (Reason 12 runs VST3 — free options: Airwindows fuzz, Valhalla Supermassive, $0).
